## Prof working on seeing-eye glove

P42086  
GUELPH (CP) — Researchers at the University of Guelph are developing a camera-assisted navigation system for the visually impaired.

The technology is "the logical extension of the walking cane," said Prof. John Zelek.

The system provides visually impaired people with tactile feedback about their immediate environment.

Two mini video cameras wired to a portable computer — all of which can be worn on the user's body — feed information into a special glove worn by the user.

The glove has vibrating motors sewn into each finger; they send impulses to the wearer, warning of obstacles and terrain fluctuations ahead.

"Traditional navigation systems provide auditory feedback, and they usually have a steep learning curve and overburden the auditory channel," said Zelek. "We wanted our system to be intuitive for the user."

Images from the cameras are processed in the computer and translated into information about the location of obstacles within the camera's range, up to about nine metres.

Then, the buzzer on the finger corresponding to the direction of that obstacle is activated.

For example, if the glove is worn on the left hand, an obstruction lying straight ahead would trigger the buzzer on the middle finger. If the obstacle is just to the right

of centre, the buzzer on the index finger would vibrate.

"The stimulus on their fingers is used to direct the user around obstructions in their path," said Zelek, who is also investigating possible new methods of conveying terrain information through a subset of the buzzers.

Zelek's technique of acquiring information about the environment is unique because of his use of dual cameras, which perceive depth like a pair of 3-D glasses.

Traditional techniques of information-gathering usually employ sonar or ultrasound waves, which are bounced around objects in a room, similar to a bat's method of navigation.

GUELPH, Ont. (CP) —  
Researchers at the University of  
Guelph are developing a camera-  
assisted navigation system for the  
visually impaired.

The technology is "the logical  
extension of the walking cane,"  
said Prof. John Zelek.

The system provides visually  
impaired people with tactile feed-  
back about their immediate envi-  
ronment.

Two mini video cameras wired  
to a portable computer — all of  
which can be worn on the user's  
body — feed information into a  
special glove worn by the user.

The glove has vibrating motors  
sewn into each finger; they send  
impulses to the wearer, warning  
of obstacles and terrain fluctua-  
tions ahead.

"Traditional navigation systems  
provide auditory feedback, and  
they usually have a steep learning  
curve and overburden the audio-  
visually channel," said Zelek. "We  
wanted our system to be intuitive  
for the user."

Images from the cameras are  
processed in the computer and  
translated into information about  
the location of obstacles within the  
camera's range, up to about nine  
metres.

Then, the buzzer on the finger  
corresponding to the direction of  
that obstacle is activated.

For example, if the glove is worn  
on the left hand, an obstruction  
lying straight ahead would trigger  
the buzzer on the middle finger.  
...if the obstacle is just to the right

of centre, the buzzer on the index  
finger would vibrate.

"The stimulus on their fingers is  
used to direct the user around  
obstructions in their path," said  
Zelek, who is also investigating  
possible new methods of convey-  
ing terrain information through a  
subset of the buzzers.

Zelek's technique of acquiring  
information about the environ-  
ment is unique because of his use  
of dual cameras, which perceive  
depth like a pair of 3-D glasses.

Traditional techniques of infor-  
mation-gathering usually employ  
sonar or ultrasound waves, which  
are bounced around objects in the  
room, similar to a bat's method of  
navigation.

But these methods of sensing  
can be easily foiled by complex  
surroundings, such as a room full  
of people, where movement cre-  
ates multiple signals and provides  
little useful information about  
obstacles.

"In the case of sonar, busy envi-  
ronments cause multiple signals to  
get back to the user, which can get  
confusing," Zelek said.

As well, sonar and ultrasound  
systems consume a lot of energy  
and need to be recharged every  
few hours.

Zelek and his research team  
decided their navigation system  
had to be wearable, comfortable  
and affordable.

"If it isn't comfortable, no one is  
going to want to use it," he said.  
"The system can't intrude on the  
user's daily activities."
